Logging Operation Notes:

Logging was conducted with a centralizer on the sondes. All measurements are referenced to ground surface.

Analysis Notes:

Pre-run and post-run verifications for the logging systems were performed before and after each day's data acquisition. The acceptance criteria were met.

A casing correction for a 1/2-in.-thick casing was applied to the SGLS data. Data acquired below 235.4 ft were corrected for water.

The moisture data are reported in counts per second (cps) as there is no valid calibration available for the casings used in this borehole. The data reflect relative moisture content.

SGLS spectra were processed in batch mode using APTEC SUPERVISOR to identify individual energy peaks and determine count rates. Concentrations were calculated with EXCEL worksheet templates identified as G4LDec07.xls using efficiency functions and corrections for casing, dead time, and water as determined from annual calibrations.

Results and Interpretations:

Cs-137 was detected near the ground surface and between 11 and 34 ft. The maximum concentration was measured at approximately 3400 pCi/g at 16 ft.

Co-60 was detected from 31 to 52 ft, from 81 to 110 ft and at 139 and 231 ft. The maximum concentration was approximately 1 pCi/g at 41 ft.

MDLs for processed uranium (U-238 and U-235) are plotted because some investigators believe the 216-BY cribs may be a source of uranium contamination in the groundwater in the area. A few detections of uranium were identified using the routine processing software. However, further inspection of the individual spectra showed no full energy peaks. Therefore, no uranium was detected in the vadose zone.

Moisture data indicate relatively high moisture at a few depth locations, which may indicate thin intervals of fine grained sediment.

Repeat sections acquired for each logging system indicate good repeatability.
